CYCLISTIC BIKE-SHARE

Member vs. Casual Rider Behavior Analysis

Capstone case study. Cyclistic is a fictional company; the analysis uses public Divvy trip data.

Executive Summary

Cyclistic's leadership wants to grow profitability by converting existing casual riders (customers who pay per ride or per day) into annual members, rather than acquiring an entirely new customer base. This report establishes the data foundation for that effort by answering one question: how do annual members and casual riders use Cyclistic bikes differently? The analysis covers 4,050,230 trips (1,485,568 casual and 2,564,662 member) from February–August 2026, the most recent continuous seven-month window in the available data.

Three differences emerged:

- **Duration:** Casual riders take longer and more variable trips (median 11 vs. 9 min; mean 18.4 vs. 12.2 min), and trips over 60 minutes are about six times more common (4.1% vs. 0.7%). The overall gap is modest (a randomly chosen casual trip is longer than a randomly chosen member trip 59% of the time) but large on classic bikes (median gap of 7 min).
- **Weekly rhythm:** Casual demand concentrates on weekends (38.0% of trips, vs. a 28.6% even-split baseline) and above all on Saturday, which alone accounts for 21.8% of casual trips and is the one day when casual riders come close to matching members (49.0% of all trips that day). Casual trips are also longer on weekends. Member demand stays steady across weekdays and dips on weekends (24.1% of trips), with little change in duration (about one minute at the median).
- **Bike type:** Both groups favor electric bikes, with casual riders slightly higher (74.5% vs. 68.9%). Among casual riders, classic-bike trips are much longer than electric-bike trips (median 16 vs. 10 min), while members ride about the same length on either bike type (median 9 min).

The duration and weekend findings held under alternative filtering thresholds, alternative observation periods, and in each of the seven months (see Part 3 and Appendices C, D and F). The bike-type finding also held in every month of 2026 but is the least stable across years: the casual–member gap in electric-bike share narrowed to 0.4 points in May–August 2025 (63.6% vs. 63.2%), so it should be read as directional. Together, these patterns are consistent with casual riders using Cyclistic mainly for weekend, leisure-oriented trips and members using it as a steady weekday mode of transport. This is an inference: trip purpose is not recorded, and time of day was not analyzed. The findings are descriptive and trip-level, so they show how the groups differ, not what would cause a casual rider to convert.

Recommendations: because casual demand is most distinctive on weekends, and especially on Saturday, the marketing team's highest-leverage opportunity is to (1) design weekend-specific incentives for casual riders, with messaging segmented by rider type; and (2) validate the incentive's effect with a randomized A/B test before full rollout. Full detail in Part 5.

Part 1: Business Task

Cyclistic's leadership team aims to increase company profitability. Rather than pursuing an entirely new customer base, leadership believes the strongest opportunity lies in converting existing casual riders, customers who purchase single-ride or day passes, into annual members, since annual members already generate substantially higher profit and the casual segment is both large and stable.

Executing this conversion strategy requires an effective marketing approach, which in turn requires a clear, evidence-based understanding of the foundational question:

> **KEY FINDING:** How do annual members and casual riders use Cyclistic bikes differently?

This report answers that question through three specific sub-questions:

- Does ride duration differ between members and casual riders, and in what way?
- Does weekday vs. weekend usage behavior differ between the two groups, and in what way?
- Does bike-type preference differ between the two groups, and in what way?

Scope: findings are intended to inform the marketing team's targeting strategy, who to target, when, and with what message, for a membership-conversion campaign. This report does not address pricing strategy or the underlying motivations behind casual riders' purchasing decisions; answering those questions would require data beyond what is available in the current trip-level dataset.

Part 2: Data Source Description

This analysis uses historical trip-level data from Divvy, Chicago's bike-share system, operated by Lyft Bikes and Scooters, LLC and published publicly under the Divvy Data License Agreement. The files were obtained through the Google Data Analytics Professional Certificate capstone materials. The data is organized as individual monthly CSV files (57 files spanning June 2020 to August 2026; file names encode year and month, e.g. 202107-divvy-tripdata.csv). Each row represents one trip and includes: ride ID, bike type, start/end timestamps, start/end station, coordinates, and rider type (casual/member).

An initial review of the 2020–2026 files available for this project found that 18 of 75 possible months were not present, and that the missing months were not evenly distributed across the year (see Appendix A). To avoid overstating seasonal or weekly patterns from an unevenly represented multi-year pool, this report restricts its analysis window to the seven most recent, fully continuous months available: February through August 2026 rather than the full archive.

ROCCC Assessment

Criterion	Assessment
Reliable	Trips are recorded automatically by the operator's system, with no manual entry or self-reporting. A small share of records are invalid (negative or extreme durations) and were removed in Part 3.
Original	Data is published by the bike-share operator from its own system, not by a third-party aggregator. The files are raw and unfiltered: they still contain very short trips (under 60 seconds) and extremely long trips (over 24 hours), which were handled in Part 3.
Comprehensive	Covers both rider segments (casual, member) and all fields required for this analysis. The full multi-year archive has gaps in month coverage; this is mitigated by restricting the analysis window to a verified continuous 7-month period (see Part 3).
Current	Data extends through August 2026, reflecting present-day usage patterns.
Cited	Source: Divvy System Data (https://divvybikes.com/system-data), published by Lyft Bikes and Scooters, LLC under the Divvy Data License Agreement; files obtained via the Google Data Analytics Professional Certificate capstone, accessed 24 September 2026.

Privacy note: per the data provider's policy, the dataset contains no personally identifiable information. Individual trips cannot be linked to a single rider across multiple trips. As a result, this analysis cannot determine whether casual riders purchase multiple single-ride or day passes, nor whether they reside within Cyclistic's service area. These are acknowledged limitations of the dataset itself, not shortcomings of the cleaning or analysis process.

Part 3: Data Cleaning Process

Tooling: R, with SQL used for diagnostic checks and summary aggregation on the full dataset.

3.1 Cleaning Steps

- Parsed and standardized all timestamp formats; computed ride_length (minutes) as end time minus start time.
- Removed duplicate ride IDs, keeping one record per trip.
- Removed trips with negative duration, trips under 1 minute (likely false starts), and trips over 24 hours (likely lost or malfunctioning equipment).
- Restricted the working dataset to February - August 2026, the most recent continuous 7-month window, for all weekly and monthly comparisons.
- All date attributes (day of week, month, weekend flag) are based on trip start time. Timestamps are recorded to the minute, so durations are whole minutes.

3.2 Impact of Cleaning

Rider type	Total trips	Trips removed	% removed	% <1 min	% >24 h
Casual	1,518,910	33,342	2.20%	2.00%	0.19%
Member	2,601,307	36,645	1.41%	1.38%	0.02%

Table 1. Effect of filtering on each rider segment.

Removal rates are small (under 2.5%) and comparable between the two groups, so excluding these trips does not meaningfully bias the comparison between casual and member riders.

3.3 Robustness Checks

Because the sample is very large (over 4 million trips), p-values are uninformative: almost any difference would be "significant". Uncertainty is instead expressed with 95% bootstrap confidence intervals (resampling days rather than trips, 1,000-2,000 draws) and effect-size measures (see Appendix C). Days are used as the resampling unit because trips on the same day share weather and demand conditions and are not independent.

- Data-completeness check: across 212 days in the analysis window, even the lowest-volume single day still recorded 2,442 trips (vs. a daily high of 39,813), indicating no abnormal gaps within the chosen period (see Appendix B).
- Threshold sensitivity: the duration comparison was re-run using alternate exclusion thresholds (removing trips under 2 or 5 minutes; capping at 3 or 6 hours instead of 24). The core finding, that casual trips run longer than member trips, held under every threshold tested (see Appendix C).
- Observation-period sensitivity check: core comparisons were re-run across alternative periods (May-August 2026, May-August 2025, and August 2021-July 2022). The direction of longer casual duration and higher casual weekend activity remained consistent in all of them. The casual electric-bike share was also higher in every period, but the gap narrowed to under one percentage point in May-August 2025 (63.6% vs. 63.2%), so this finding is the least stable (see Appendix D).
- **Month-by-month check:** the main comparisons were repeated separately for each of the seven months. In all seven months, casual riders had longer median and mean durations, a higher weekend index, and a higher electric-bike share than members (see Appendix F).

Part 4: Summary of Analysis

4.1 Does ride duration differ between members and casual riders?

KEY FINDING: Casual riders take longer trips than members on average, and their trip lengths are more variable (P90 36 vs. 24 min).

Rider type	Trips	Mean (min)	Median (min)	Q1	Q3	P90	Mean/Median
Casual	1,485,568	18.4	11	7	20	36	1.67
Member	2,564,662	12.2	9	5	15	24	1.35

Table 2. Descriptive statistics of ride duration by rider type.

Members account for the majority of trips in the period (2,564,662 vs. 1,485,568; casual trips make up 36.7% of the total). Member trips are consistently shorter: median 9 vs. 11 minutes, mean 12.2 vs. 18.4 minutes and less dispersed (interquartile range of 10 minutes vs. 13 minutes; 90th percentile 24 vs. 36 minutes). The wider gap between mean and median for casual riders (1.67 vs. 1.35) indicates a longer right tail: a subset of unusually long casual trips pulls the average upward.

Rider type	Duration bracket	Trips	% of group
Casual	Under 5 min	196,026	13.2%
Casual	5–10 min	416,867	28.1%
Casual	10–20 min	476,491	32.1%
Casual	20–30 min	184,905	12.4%
Casual	30–60 min	150,061	10.1%
Casual	60+ min	61,218	4.1%
Member	Under 5 min	498,224	19.4%
Member	5–10 min	881,529	34.4%
Member	10–20 min	791,286	30.9%
Member	20–30 min	242,916	9.5%
Member	30–60 min	133,508	5.2%
Member	60+ min	17,199	0.7%

Table 3. Distribution of trips by duration bracket and rider type.

Both groups cluster mainly in the 5-20 minute range (casual 60.2%, member 65.3%). The clearest difference sits at the two tails: members have more very short trips (under 10 minutes: 53.8% vs. 41.3% for casual), while casual riders have a far longer tail (20+ minutes: 26.6% vs. 15.4%; 60+ minutes: 4.1% vs. 0.7%, roughly six times higher).

4.2 Does weekday vs. weekend usage behavior differ between the two groups?

KEY FINDING: Casual usage peaks on weekends, especially Saturday (21.8% of casual trips; Friday–Sunday together account for 53.4%), and casual trips are longer on weekends within both bike types. Member demand, in contrast, stays steady across weekdays, tapers off on weekends, and shows little change in trip duration (about one minute at the median).

Day	Rider type	Trips	Days counted	Avg trips/day	% of group
Sun	Casual	240,833	31	7,769	16.2%
Mon	Casual	173,554	31	5,599	11.7%
Tue	Casual	168,449	30	5,615	11.3%
Wed	Casual	170,016	30	5,667	11.4%
Thu	Casual	179,793	30	5,993	12.1%
Fri	Casual	229,084	30	7,636	15.4%
Sat	Casual	323,839	30	10,795	21.8%
Sun	Member	281,803	31	9,090	11.0%
Mon	Member	367,993	31	11,871	14.3%
Tue	Member	404,792	30	13,493	15.8%
Wed	Member	403,897	30	13,463	15.7%
Thu	Member	398,351	30	13,278	15.5%
Fri	Member	371,347	30	12,378	14.5%
Sat	Member	336,479	30	11,216	13.1%

Table 4. Trip volume by individual day of week and rider type.

Casual ridership is low and flat from Monday to Thursday (each day accounts for 11–12% of casual trips), climbs on Friday (15.4%), and peaks on Saturday (21.8%, the single highest day of the week) before easing on Sunday (16.2%). Member ridership, by contrast, stays high and comparatively flat across weekdays, peaking on Tuesday through Thursday (roughly 13,400 trips/day), and falls on

weekends: modestly on Saturday (11,216) and more sharply on Sunday (9,090), the lowest-volume day for members.

Rider type	Day type	Trips	Days	Avg trips/day	% of group
Casual	Weekend (Sat–Sun)	564,672	61	9,257	38.0%
Casual	Weekday (Mon–Fri)	920,896	151	6,099	62.0%
Member	Weekend (Sat–Sun)	618,282	61	10,136	24.1%
Member	Weekday (Mon–Fri)	1,946,380	151	12,890	75.9%

Table 5. Trip volume by day type and rider type.

If usage were spread evenly across all seven days, weekends (2 of 7 days) would account for 28.6% of trips. Casual riders exceed that baseline substantially: 38.0% of their trips fall on weekends, and average daily weekend volume runs about 52% higher than on weekdays (9,257 vs. 6,099 trips/day; weekend index 1.52). Members fall below the baseline: only 24.1% of their trips occur on weekends, and average daily weekend volume is roughly 21% lower than on weekdays (10,136 vs. 12,890 trips/day; index 0.79).

Weekend trips are also longer for casual riders within each bike type (Table 6a): on classic bikes the median rises from 15 to 18 minutes and on electric bikes from 10 to 12 minutes, whereas members change by about one minute (classic 9 to 10, electric 8 to 9). Casual riders do shift slightly toward classic bikes on weekends (27.9% of weekend trips vs. 24.1% on weekdays), but the longer durations are also visible within each bike type.

Bike type	Rider type	Day type	Trips	Median (min)	Mean (min)	P90 (min)
Classic bike	Casual	Weekend (Sat–Sun)	157,415	18	31.7	63
Classic bike	Casual	Weekday (Mon–Fri)	221,849	15	27.3	55
Classic bike	Member	Weekend (Sat–Sun)	194,732	10	15.3	31
Classic bike	Member	Weekday (Mon–Fri)	602,816	9	13.4	27
Electric bike	Casual	Weekend (Sat–Sun)	407,257	12	16.5	34
Electric bike	Casual	Weekday (Mon–Fri)	699,047	10	13.7	27
Electric bike	Member	Weekend (Sat–Sun)	423,550	9	12.5	24
Electric bike	Member	Weekday (Mon–Fri)	1,343,564	8	11.1	21

Table 6a. Ride duration by bike type, rider type, and day type

Day	Casual riders		Member riders	
	Median (min)	Mean (min)	Median (min)	Mean (min)
Mon	11	18.4	9	11.9
Tue	10	16.2	9	11.7
Wed	10	15.6	9	11.6
Thu	10	16.1	9	11.7
Fri	11	18.1	9	12.1
Sat	13	20.7	10	13.5
Sun	13	20.8	9	13.3

Table 6b. Trip duration by day of week and rider type (weekend days shaded).

Ride duration follows the same pattern by day (Table 6b): casual trip length rises on Saturday and Sunday (median 13 min vs. 10–11 min on weekdays; mean 20.7–20.8 vs. 15.6–18.4 min), while member duration stays close to flat all week (median 9 min every day except Saturday, when it is 10; mean 11.6–13.5 min). On Saturdays, casual ridership comes closest to matching member ridership: casual riders

take 10,795 trips per day versus 11,216 for members, and make up 49.0% of combined volume that day, well above the 36.7% period-wide share.

The weekday activity index, which removes the February–August seasonal rise, confirms that Saturday is the one day when casual activity is clearly above average (index 1.43, 95% CI 1.27–1.60), while member activity falls below average on weekends (Saturday 0.89, Sunday 0.74). For casual riders, Friday (1.10) and Sunday (1.09) are only mildly elevated, and their confidence intervals include 1.00 (see Appendix E).

4.3 Does bike-type preference differ between members and casual riders?

> **KEY FINDING** Both casual and member riders prefer electric bikes. Among members, median trip duration is nearly identical across both bike types; among casual riders, classic-bike trips run noticeably longer than electric-bike trips.

Rider type	Bike type	Trips	% of group	Median duration (min)
Casual	Electric bike	1,106,304	74.5%	10
Casual	Classic bike	379,264	25.5%	16
Member	Electric bike	1,767,114	68.9%	9
Member	Classic bike	797,548	31.1%	9

Table 7. Bike-type usage and median duration by rider type.

Electric bikes account for the majority of trips in both groups, with casual riders showing a slightly higher share (74.5% vs. 68.9%, a 5.6-point gap). When casual riders choose a classic bike, their median trip (16 minutes) is markedly longer than on an electric bike (10 minutes), a gap not present among members, whose median duration holds at roughly 9 minutes regardless of bike type. This pattern is consistent with, though not direct proof of, classic bikes being used more often for leisure trips among casual riders; confirming the underlying reason would require additional data (e.g., trip purpose or station-level land use).

Part 5: Recommendations

1. Design weekend-specific incentives for casual riders. Casual usage peaks on weekends, especially Saturday (21.8% of casual trips; Friday-Sunday together account for 53.4%), and trips are longer on those days. Offer casual riders a limited-time discount on annual membership, or bonus ride time on

weekend trips, conditional on upgrading, at the moment they are most engaged. Messaging should be segmented by rider type rather than run as one generic campaign.

2. Validate with an A/B test before full rollout. Offer the weekend incentive to a random sample of casual riders, withhold it from a control group, and compare conversion rates, this isolates the incentive's real effect from seasonal or other confounding factors. Randomize at the account or app-user level (or by station cluster if accounts cannot be identified), use conversion to annual membership within 30–60 days as the primary metric, run the test for several weeks in peak season with sample size set by a power analysis, and track incentive cost per conversion.

Part 6: Limitations of the Analysis

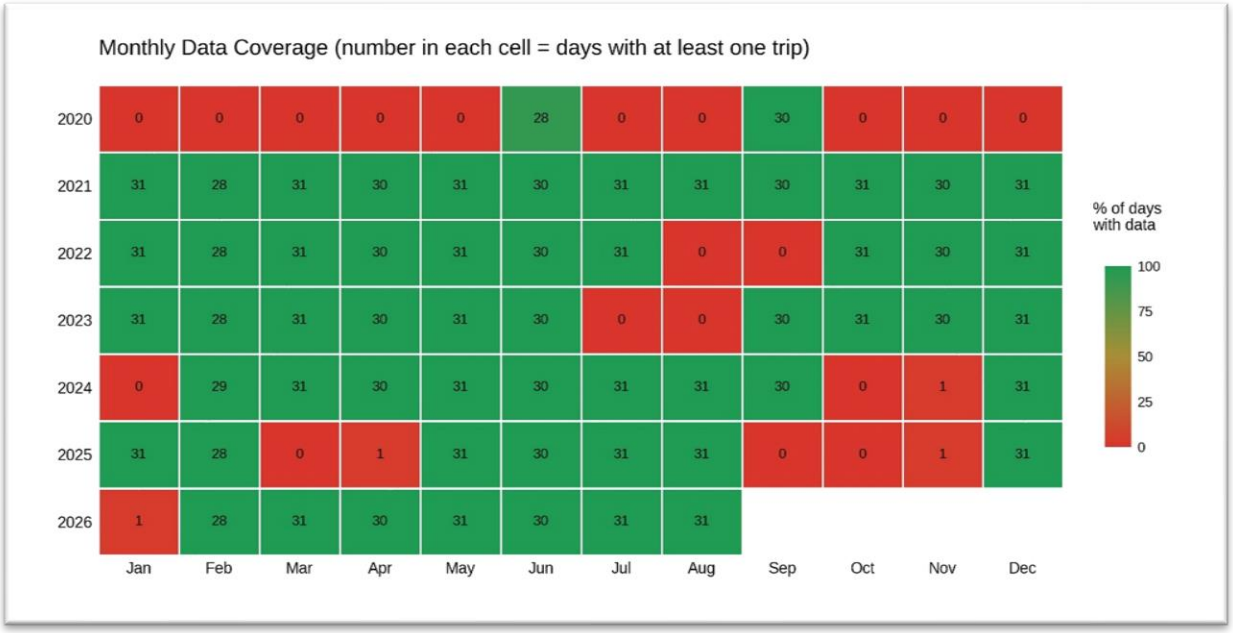

Limitation	Implication for interpretation
No individual-level rider history	The dataset does not provide a persistent rider identifier. Individual trips therefore cannot be linked across time, so the analysis cannot determine whether a casual rider is a frequent repeat customer, how often an individual rides, or whether the same person makes both weekday and weekend trips.
No direct conversion evidence	The analysis compares existing casual and member behavior but does not observe who later becomes a member. Therefore, the results identify characteristics of the casual segment rather than predictors of actual membership conversion.
No pricing or revenue variables	The dataset used here does not contain the information needed to estimate revenue, willingness to pay, discount sensitivity, or the financial return of a membership promotion. Specific pricing or discount recommendations would require additional business and transaction data.
Limited analysis window	The main analysis uses February–August 2026 because this is the most recent continuous seven-month period available. Although robustness checks using other periods support the weekend pattern, duration and bike-type measures vary across periods, so the main numerical estimates should not automatically be generalized to every season or future period.
Observational analysis	The analysis is descriptive and observational. Differences between casual and member riders should not be interpreted as causal effects. The data cannot establish that weekend messaging, longer rides, or bike type causes a rider to become a member.
Trip-level rather than customer-level interpretation	All comparisons are based on trips. A rider who takes many trips contributes many observations, so trip-level results describe usage volume rather than the characteristics of individual people.

Appendices

The following tables provide the full sensitivity-check and robustness-check detail referenced in Part 3 and Part 4. They are included for verification purposes and are not required to follow the main findings and recommendations above.

Table E1. Weekday activity index by rider type (index = 1.00 means average activity for that rider type; values above/below 1.00 indicate above/below-average activity on that day). Lower/upper bound = 95% confidence interval. The weekday index divides each day's trip count by the centered 7-day moving average for the same rider type, which removes the Feb–Aug seasonal rise. The first and last three days of the window have no full 7-day average and are excluded (206 of 212 days; "Days counted" therefore differs from Table 4, which uses raw counts for all 212 days). Confidence intervals are 95% bootstrap intervals (2,000 resamples of days).

Appendix F: Month-by-Month Consistency Check

The main comparisons were repeated separately for each of the seven months in the analysis window to confirm that no single month drives the results.

Month	Casual share of trips (%)	Median duration (min)		Mean duration (min)		Weekend index		Electric-bike share (%)	
		Casual	Member	Casual	Member	Casual	Member	Casual	Member
2026-02	20.3	8	7	14.0	10.7	0.93	0.56	71.5	65.1
2026-03	27.6	10	8	16.7	11.2	1.64	0.80	72.5	68.0
2026-04	29.2	10	8	16.5	11.4	1.17	0.67	73.8	68.1
2026-05	37.3	12	9	19.5	12.4	1.54	0.81	72.4	67.8
2026-06	40.2	12	9	19.2	12.7	1.73	0.86	72.6	67.7
2026-07	41.0	12	9	18.9	12.5	1.59	0.84	75.3	70.3

Table F1. Month-by-month comparison of casual and member riders, February-August 2026. Weekend index = average trips per weekend day ÷ average trips per weekday.

In all seven months, casual riders had a higher median and mean trip duration, a higher weekend index, and a higher electric-bike share than members, so the direction of each finding does not depend on any single month.

The size of the gaps varies with season. The casual share of trips rises from 20.3% in February to about 40% from June to August, so the period-wide share is weighted toward warmer months. The casual weekend index ranges from 0.93 in February (no weekend lift in winter) to 1.73 in June, while the member index stays between 0.56 and 0.86. The median duration gap widens from 1 minute in February to 3 minutes from May onward. The electric-bike gap is steady at 4.5–6.4 percentage points in every month.
